Bucket-Sort and Radix-Sort

Bucket-Sort

- Let S be a sequence of n (key, element) items with keys in the range [0, N-1]
- Bucket-sort uses the keys as indices into an auxiliary array B of sequences (buckets)

Phase 1: Empty sequence S by moving each item (k, o) into its bucket B[k]

Phase 2: For i = 0, ..., N - 1, move the items of bucket B[i] to the end of sequence S

- Analysis:
 - Phase 1 takes O(n) time
 - Phase 2 takes *O*(n+*N*) time

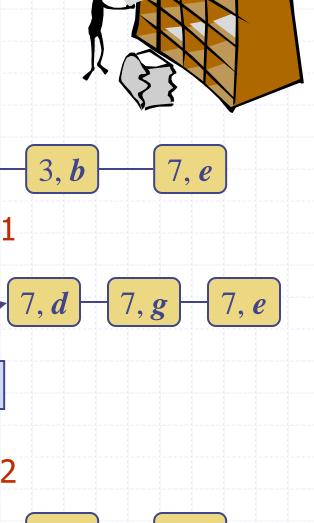

Bucket-sort takes O(n + N) time

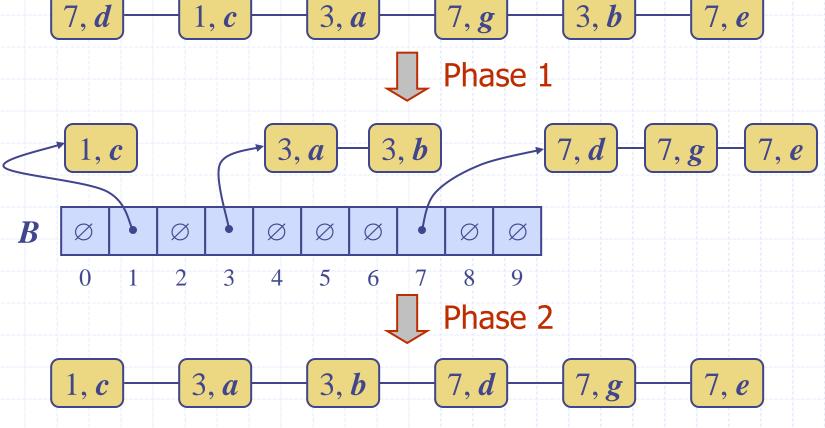

```
Algorithm bucketSort(S, N)
    Input sequence S of (key, element)
        items with keys in the range
        [0, N-1]
    Output sequence S sorted by
        increasing keys
    B \leftarrow array of N empty sequences
    while \neg S.isEmpty()
        f \leftarrow S.first()
        (k, o) \leftarrow S.remove(f)
        B[k].insertLast((k, o))
    for i \leftarrow 0 to N-1
        while \neg B[i]. is Empty()
             f \leftarrow B[i].first()
             (k, o) \leftarrow B[i].remove(f)
             S.insertLast((k, o))
```

Example

♦ Key range [0, 9]

Properties and Extensions

- Key-type Property
 - The keys are used as integer indices into an array and cannot be arbitrary objects
 - No external comparator!
- Stable Sort Property
 - The relative order of any two items with the same key is preserved after the execution of the algorithm

Extensions

- Integer keys in the range [a, b]
 - Put item (k, o) into bucket B[k-a]
- String keys from a set D of possible strings, where D has constant size (e.g., names of the 50 U.S. states)
 - Sort D and compute the rank r(k)
 of each string k of D in the sorted
 sequence
 - Put item (k, o) into bucketB[r(k)]
- Any key-set that can essentially be mapped to a contiguous set of integers

Example Application

- You are hired by a new startup company
- Each person a database (of size 1 million) is uniquely keyed by name or SSN
- Database is continually reordered based on a proprietary algorithm
- They ask you to write a program which enables blazingly fast re-sorting of the database by SSN
 - List of people changes slightly each time, but SSN are fixed
 - The order of the people changes drastically (i.e., is not "almost sorted")

Options?

- 1. Use an $O(N^2)$ algorithm
- 2. Use an O(NlogN) algorithm
- 3. Invent an O(N) algorithm!

If you accomplish option (3) you get a huge bonus.

What can you do?

Bucket-sort:

- a. Map SSN to a compact list of sequential IDs
- b. Use compact IDs to bucket sort!

Next topic: Lexicographic Order

- lacktriangle A *d*-tuple is a sequence of *d* keys $(k_1, k_2, ..., k_d)$, where key k_i is said to be the *i*-th dimension of the tuple
- Example:
 - The Cartesian coordinates of a point in space are a 3-tuple
- The lexicographic order of two d-tuples is recursively defined as follows

$$(x_1, x_2, ..., x_d) < (y_1, y_2, ..., y_d)$$

$$x_1 < y_1 \lor x_1 = y_1 \land (x_2, ..., x_d) < (y_2, ..., y_d)$$

i.e., the tuples are compared by the first dimension, then by the second dimension, etc.

Lexicographic-Sort

- lacktriangle Let C_i be the comparator that compares two tuples by their i-th dimension
- Let stableSort(S, C) be a stable sorting algorithm that uses comparator C
- Lexicographic-sort sorts a sequence of d-tuples in lexicographic order by executing d times algorithm stableSort, one per dimension
- Lexicographic-sort runs in O(dT(n)) time, where T(n) is the running time of stableSort

Algorithm *lexicographicSort*(S)

Input sequence *S* of *d*-tuples **Output** sequence *S* sorted in lexicographic order

for $i \leftarrow d$ downto 1 $stableSort(S, C_i)$

Example:

(7,4,6) (5,1,5) (2,4,6) (2,1,4) (3,2,4)

(2, 1, 4) (3, 2, 4) (5,1,5) (7,4,6) (2,4,6)

(2, 1, 4) (5,1,5) (3, 2, 4) (7,4,6) (2,4,6)

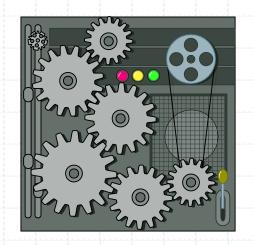

(2, 1, 4) (2,4,6) (3, 2, 4) (5,1,5) (7,4,6)

Why do you sort starting with the last dimension?

Like numbers/bits: start with LSB to MSB...

Welcome to Radix-Sort

- Radix-sort is a specialization of lexicographic-sort that uses bucket-sort as the stable sorting algorithm in each dimension
- Radix-sort is applicable to tuples where the keys in each dimension i are integers in the range [0, N-1]
- Radix-sort runs in time
 - O(d(n+N))

Algorithm radixSort(S, N)

Input sequence *S* of *d*-tuples such that $(0, ..., 0) \le (x_1, ..., x_d)$ and $(x_1, ..., x_d) \le (N-1, ..., N-1)$ for each tuple $(x_1, ..., x_d)$ in *S*

Output sequence *S* sorted in lexicographic order

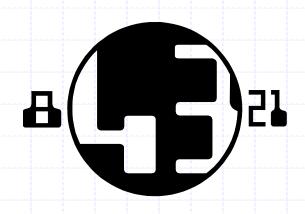

for $i \leftarrow d$ downto 1 bucketSort(S, N)

Radix-Sort for Binary Numbers

Consider a sequence of nb-bit integers

$$\boldsymbol{x} = \boldsymbol{x_{b-1}} \dots \boldsymbol{x_1} \boldsymbol{x_0}$$

- What is the tuple size?
 - b
- What is the key range?
 - N=2 (i.e., 0 or 1)
- This application of the radix-sort algorithm runs in what time?
 - O(b(n+2)) = O(n) for b constant
- For example, we can sort a sequence of 32-bit integers in linear time!

Algorithm *binaryRadixSort(S)*

Input sequence *S* of *b*-bit integers

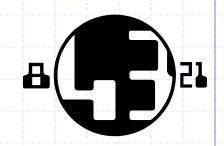

Output sequence S sorted replace each element x of S with the item (0, x)

for
$$i \leftarrow 0$$
 to $b-1$

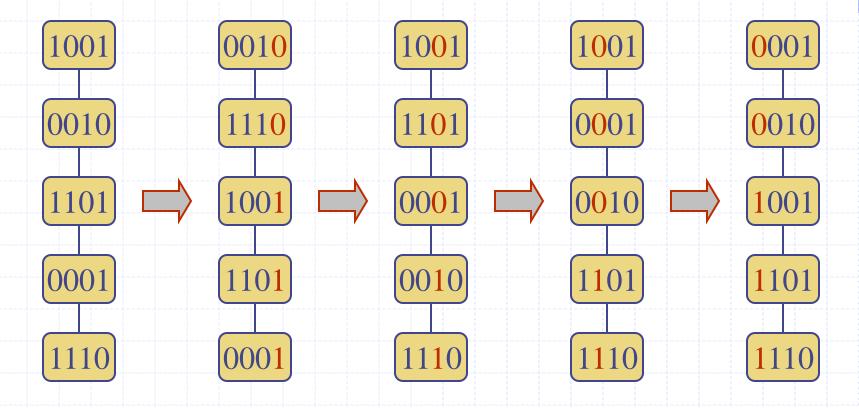

replace the key k of each item (k, x) of S with bit x_i of x

bucketSort(S, 2)

Example

Sorting a sequence of 4-bit integers

Summary of Sorting Algorithms

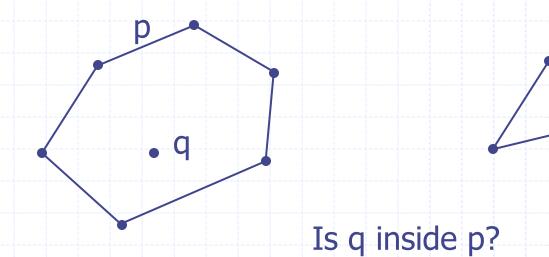

Algorithm	Time	Notes
selection-sort	$O(n^2)$	in-placeslow (good for small inputs)
insertion-sort	$O(n^2)$	in-place, O(n) for almost sortedslow (good for small inputs)
quick-sort	$O(n \log n)$ expected	in-place, randomizedfastest (good for large inputs)
merge-sort	$O(n \log n)$	sequential data accessfast (good for huge inputs)
bucket-sort	O(n+N)	 only for contiguous integer keys [0, N-1] uses space proportional to key range
radix-sort	O(d(n+N))	◆ good for sorting numbers◆ O(n) for N=2 (binary) and d constant

Geometry and Sorting

- Sorting is not only useful to organize keys
- Geometric operations and sorting are also tightly linked
- Breaking the O(n log n) boundary would also benefit geometric operations
 - Or, said another way, there are also geometric arguments to the $O(n \log n)$ boundary

Point-in-Polygon

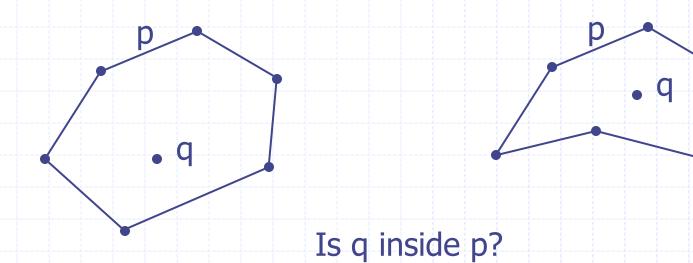

Given a set of n-points that form a closed polygon, determine if a point q is "inside" the polygon p

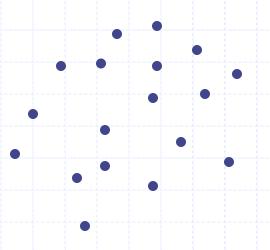

Bucket-Sort and Radix-Sort

Point-in-Polygon

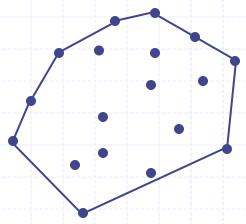

- Straightforward O(n) inclusion algorithm
- For convex polygon case, we can be more efficient...

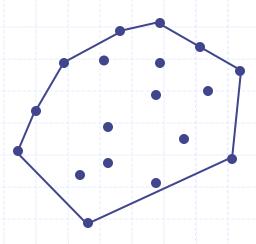

Given an array of points P, find the convex hull, e.g., the "shrink wrap"

Useful for many applications: point inclusion, triangulation, surface reconstruction (in 3D), etc.

- How do you this? Ideas?
- What is the complexity?

- Best known solution is O(n log n)
- Corresponds to a two-dimensional sort (in 2D)
 - Thus if could do better than O(n log n), could sort better than O(n log n)
